1 Section 3.2

2 Section 3.3

2.1 Problem **3.6**

For the AR(2) model given by $x_t = -.9x_{t-2} + w_t$, find the roots of the autoregressive polynomial, and then sketch the ACF, $\rho(h)$.

The polynomial is $x_t + 0.9x_{t-2} = w_t$

```
z <- c(1, 0, .9) # coefficients of the polynomial
polyroot(z) # print out the roots</pre>
```

[1] 0+1.054093i 0-1.054093i

```
abs(polyroot(z))
```

[1] 1.054093 1.054093

All the roots are larger than 1 meaning that the model is causal.

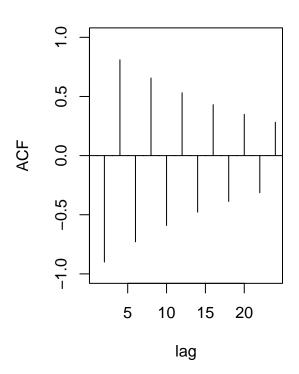

```
ACF <- ARMAacf(ar=c(0, -.9), ma=0, 24)[-1] # we exclude the lag 0

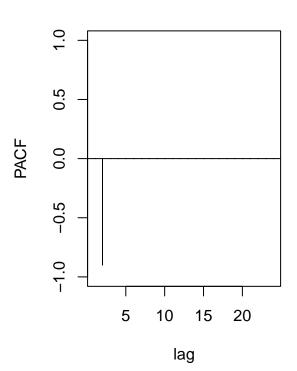

PACF <- ARMAacf(ar=c(0, -.9), ma=0, 24, pacf=TRUE)

par(mfrow=c(1,2))

plot(ACF, type="h", xlab="lag", ylim=c(-1,1)); abline(h=0)

plot(PACF, type="h", xlab="lag", ylim=c(-1,1)); abline(h=0)
```

2.2 Example **3.11**

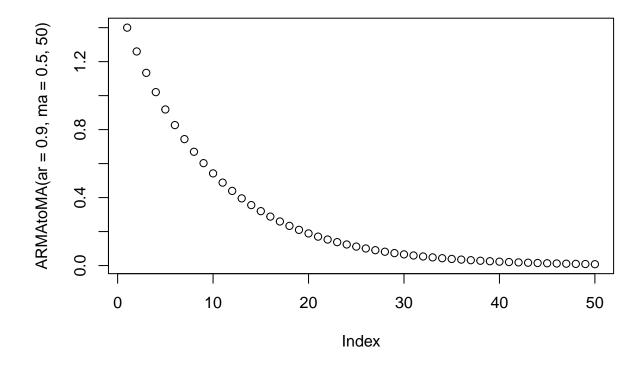

The ψ -weights for an ARMA Model.

Consider $x_t = .9x_{t-1} + .5w_{t-1} + w_t$

ARMAtoMA(ar=.9, ma=.5, 50) # for a list, first 50 psi-weights

```

```
plot(ARMAtoMA(ar=.9, ma=.5, 50)) # for a graph
```

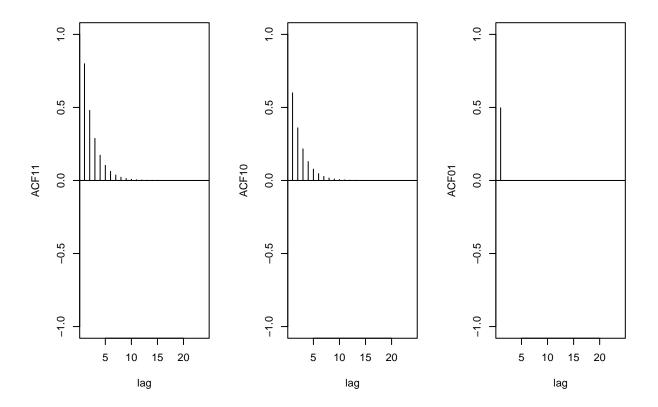

3 Section 3.4

3.1 **Problem 3.8**

Verify the calculations for the autocorrelation function of an ARMA(1, 1) process given in Example 3.13. Compare the form with that of the ACF for the ARMA(1,0) and the ARMA(0,1) series. Plot (or sketch) the ACFs of the three series on the same graph for $\phi = .6$, $\theta = .9$, and comment on the diagnostic capabilities of the ACF in this case.

$$x_t = \phi x_{t-1} + \theta w_{t-1} + w_t$$

```
phi=.6
theta=.9
ACF11 <- ARMAacf(ar=c(phi), ma=c(theta), 24)[-1]
ACF10 <- ARMAacf(ar=c(phi), ma=0, 24)[-1]
ACF01 <- ARMAacf(ar=0, ma=theta, 24)[-1]
par(mfrow=c(1,3))
plot(ACF11, type="h", xlab="lag", ylim=c(-1,1)); abline(h=0)
plot(ACF10, type="h", xlab="lag", ylim=c(-1,1)); abline(h=0)
plot(ACF01, type="h", xlab="lag", ylim=c(-1,1)); abline(h=0)</pre>
```

3.2 Problem **3.9**

Generate n = 100 observations from each of the three models discussed in Problem 3.8. Compute the sample ACF for each model and compare it to the theoretical values. Compute the sample PACF for each of the generated series and compare the sample ACFs and PACFs with the general results given in Table 3.1.

```
ARMA11 <- arima.sim(list(ar=c(phi), ma=c(theta)), n=100, rand.gen = rnorm, sd = 1)

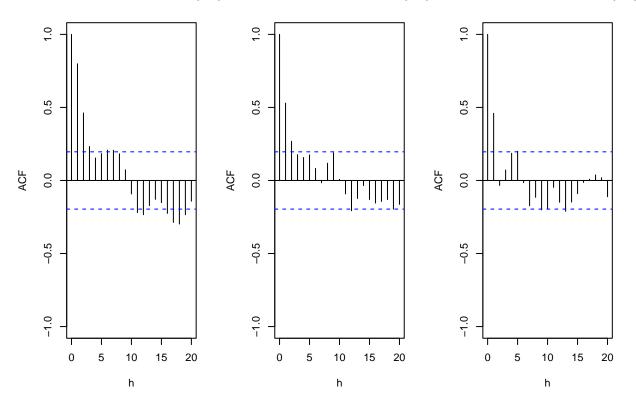

ARMA10 <- arima.sim(list(ar=c(phi), ma=0), n=100, rand.gen = rnorm, sd=1)

ARMA01 <- arima.sim(list(ar=0, ma=c(theta)), n=100, rand.gen = rnorm, sd=1)
```

Warning in min(Mod(polyroot(c(1, -model\$ar)))): no non-missing arguments to ## min; returning Inf

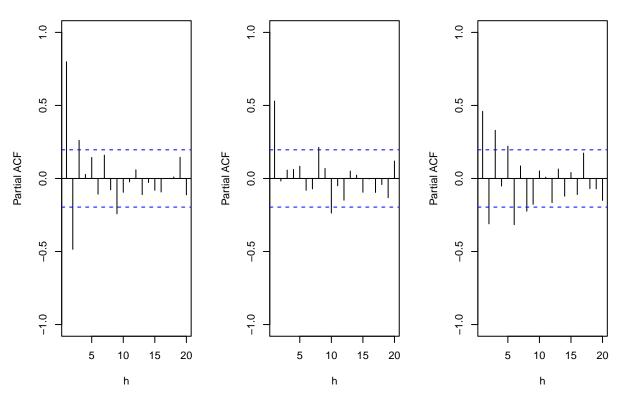

```
# estimated acf
par(mfrow=c(1,3))

    ylim=c(-1,1), main= "Estimated ACF of ARMA(1,0)")
acf(ARMA01, type="correlation", lag.max = 20, xlab="h",
    ylim=c(-1,1), main= "Estimated ACF of ARMA(0,1)")
```

Estimated ACF of ARMA(1,1) Estimated ACF of ARMA(1,0) Estimated ACF of ARMA(0,1)

```
# estimated pacf
#Note: acf(x = x, type = "partial") also gives the PACF plot
par(mfrow=c(1,3))
pacf(ARMA11, lag.max = 20, xlab="h",
    ylim=c(-1,1), main= "Estimated PACF of ARMA(1,1)")
pacf(ARMA10, lag.max = 20, xlab="h",
    ylim=c(-1,1), main= "Estimated PACF of ARMA(1,0)")
pacf(ARMA01, lag.max = 20, xlab="h",
    ylim=c(-1,1), main= "Estimated PACF of ARMA(0,1)")
```

4 Section 3.5

4.1 Problem 3.10

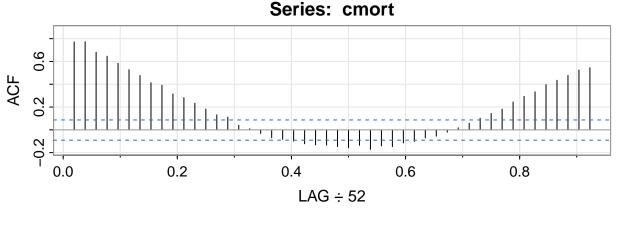

Let x_t represent the cardiovascular mortality series (cmort) discussed in Chapter 2, Example 2.2.

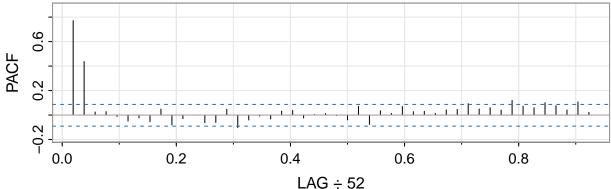

(a) Fit an AR(2) to x_t using linear regression as in Example 3.17.

AR(2):
$$x_t = \phi_0 + \phi_1 x_{t-1} + \phi_2 x_{t-2} + w_t$$

We use acf2 to print and plot the ACF and PACF.

acf2(cmort, 48) # will produce values and a graphic

Diagnostics for ARIMA(0,0,2):

- Inspection of the time plot of the standardized residuals shows no obvious patterns. Notice that there are outliers, however, with a few values exceeding 3 standard deviations in magnitude.
- The ACF of the standardized residuals shows no apparent departure from the model assumptions, and the Q-statistic is never significant at the lags shown.
- The normal Q-Q plot of the residuals shows departure from normality at the tails due to the outliers that occurred primarily in the 1950s and the early 1980s.
- The model appears to fit well except for the fact that a distribution with heavier tails than the normal distribution should be employed

```
ARMAtoMA(ar=.35, ma=0, 10) # prints psi-weights
```

```
## [1] 3.500000e-01 1.225000e-01 4.287500e-02 1.500625e-02 5.252187e-03 ## [6] 1.838266e-03 6.433930e-04 2.251875e-04 7.881564e-05 2.758547e-05
```

Notice that, in this example, not including a constant leads to the wrong conclusions about the nature of the U.S. economy. Not including a constant assume the average quarterly growth rate is zero, whereas the U.S. GNP average quarterly growth rate is about 1% (as you can see from the U.S. GNP quarterly growth rate plot).

```
# MA(2) w/o constant, you should not use this
# sarima(gnpgr, 0, 0, 2, no.constant = TRUE)

 $(1-B)x_t$

Noting the peaks at seasonal lags, h = 1s, 2s, 3s, 4s where s = 12 (i.e., h = 12, 24, 36, 48) with relatively slow decay suggests a seasonal difference

```
acf2(diff(diff(prodn), 12), 48)
```

First, concentrating on the seasonal (s = 12) lags, the characteristics of the ACF and PACF of this series tend to show a strong peak at h = 1s in the autocorrelation function, with smaller peaks appearing at h = 2s,3s, combined with peaks at h = 1s,2s,3s,4s in the partial autocorrelation function. It appears that either

- (i) the ACF is cutting off after lag 1s and the PACF is tailing off in the seasonal lags,
- (ii) the ACF is cutting off after lag 3s and the PACF is tailing off in the seasonal lags, or
- (iii) the ACF and PACF are both tailing off in the seasonal lags.

 $(1-B^{12})(1-B)x_t$

This suggests either

- (i) an SMA of order Q = 1
- (ii) an SMA of order Q = 3
- (iii) an SARMA of orders P = 2 (because of the two spikes in the PACF) and Q = 1

Next, inspecting the ACF and the PACF at the within season lags, h = 1,...,11, it appears that either

- (a) both the ACF and PACF are tailing off, or
- (b) that the PACF cuts off at lag 2.

This result indicates that we should either consider fitting a model

- (a) with both p > 0 and q > 0 for the nonseasonal components, say p = 1, q = 1, or
- (b) p = 2, q = 0.

It turns out that there is little difference in the results for case (a) and (b), but that (b) is slightly better, so we will concentrate on case (b).

Fitting the three models suggested by these observations we obtain:

- (i) $ARIMA(2,1,0) \times (0,1,1)_{12}$: AIC= 1.372, AICc= 1.378, BIC= .404
- (ii) $ARIMA(2,1,0) \times (0,1,3)_{12}$: AIC= 1.299, AICc= 1.305, BIC= .351
- (iii) $ARIMA(2,1,0) \times (2,1,1)_{12}$: AIC= 1.326, AICc= 1.332, BIC= .379

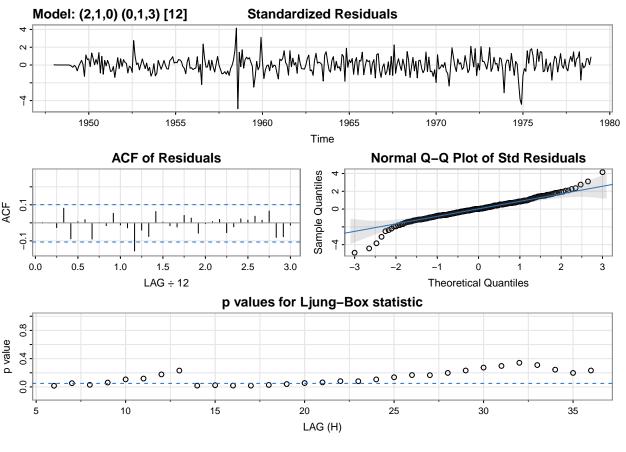

The $ARIMA(2,1,0)\times(0,1,3)_{12}$ is the preferred model, and the fitted model in this case is

$$(1-.30_{(.05)}B-.11_{(.05)}B^2)\nabla_{12}\nabla\hat{x}_t = (1-.74_{(.05)}B^{12}-.14_{(.06)}B^{24}+.28_{(.05)}B^{36})\hat{w}_t \qquad (8)$$

with $\hat{\sigma}_w^2 = 1.312$

sarima(prodn, 2, 1, 0, 0, 1, 3, 12) # fit model (ii)

The diagnostics for the fit are displayed. We note the few outliers in the series as exhibited in the plot of the standardized residuals and their normal Q-Q plot, and a small amount of autocorrelation that still remains (although not at the seasonal lags) but otherwise, the model fits well.

Finally, forecasts based on the fitted model for the next 12 months.
